Evaluation

SamplingStrata

Optimal stratification

Given a sampling frame, SamplingStrata allows to optimize its stratification when designing a sampling survey, given precision constraints on target estimates.

Three different methods

The optimization can be run by indicating three different methods, on the basis of the following:

- A. if stratification variables are categorical (or reduced to) then the method is the "atomic";
- B. if stratification variables are continuous, then the method is the "continuous";
- C. if stratification variables are continuous, and there is spatial correlation among units in the sampling frame, then the required method is the "spatial".

A. Method "atomic"

Different steps:

- 1. define the sampling frame;
- set precision constraints;
- build atomic strata;
- run optimization;
- perform evaluation;
- select the sample.

Sampling frame

Data on 2896 **Swiss** municipalities

```
library(SamplingStrata)
    data("swissmunicipalities")
     swissmunicipalities$id <-</pre>
    c(1:nrow(swissmunicipalities))
     frame <- buildFrameDF(</pre>
                df = swissmunicipalities,
                id = "id",
Stratification
                domainvalue = "REG",
variables
                TX = c("POPTOT", "HApoly"),
                Y =c("Surfacesbois", "Airind"))
```

Target variables

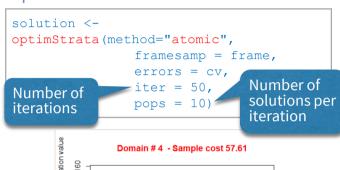

Precision constraints

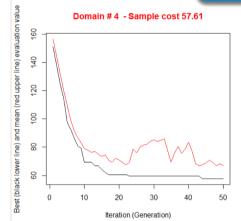

```
length(unique(frame$domainvalue))
   cv <- as.data.frame(list(</pre>
                  DOM = rep("DOM1", ndom),
                  CV1 = rep(0.10, ndom),
10% of
                  CV2 = rep(0.10, ndom),
maximum
                  domainvalue = c(1:ndom)))
expected CV
```

Atomic strata

```
strata <- buildStrataDF(frame)</pre>
```

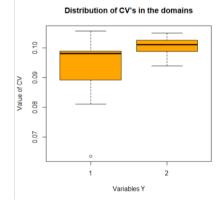

Optimization

Evaluation

```
outstrata <- solution$aggr strata</pre>
framenew <- solution$framenew</pre>
eval <- evalSolution(framenew,outstrata)</pre>
eval$coeff var
```

Sample selection

```
s <- selectSample(framenew,outstrata)
Head(s)
```

	DOMAINVALUE	STRATO	ID	X1	X2	Y1	Y2	LABEL	WEIGHTS
1	1	1	2398	241	294	101	0	1	21.38462
2	1	1	2331	267	449	215	1	1	21.38462
3	1	1	2410	237	935	471	0	1	21.38462
4	1	1	2112	370	330	98	0	1	21.38462
5	1	1	2563	173	178	16	0	1	21.38462
6	1	1	2091	382	594	338	0	1	21.38462

B. Method "continuous"

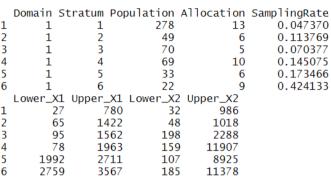

Same steps with the exception of strata building, not necessary.

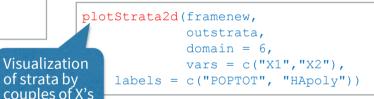

Frame definition and precision constraints settings are done in the same way than in method "atomic". One more step is in determination of the most promising number of strata with kmeans clustering.

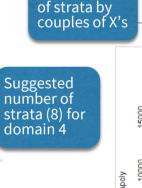

Kmeans clustering

```
kmean <- KmeansSolution2(frame=frame,</pre>
                 errors=cv,
                maxclusters = 10)
nstrat <- tapply(kmean$suggestions,</pre>
                   kmean$domainvalue,
                  FUN=function(x)
                       length(unique(x)))
sugg <- prepareSuggestion(</pre>
                 kmean = kmean,
                 frame = frame,
                nstrat = nstrat)
```

framenew <- solution\$framenew</pre> outstrata <- solution\$aggr strata</pre> ss <-summaryStrata(framenew, outstrata)</pre> head(ss)

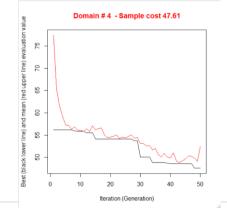

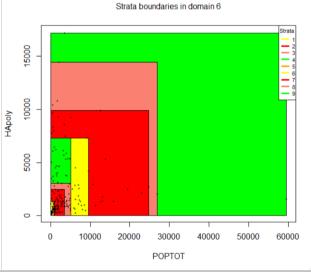

strata (8) for domain 4

Optimization

```
solution <- optimStrata (</pre>
                  method = "continuous",
                  framesamp = frame,
                  errors = cv,
Suggestion
                  nStrata = nstrat,
prepared by
                  iter = 50,
kmeans
                  pops = 10,
clustering
                  suggestions = sugg)
```

evalSolution(framenew, outstrata) eval\$coeff var

Sample selection

```
s <- selectSample(framenew, outstrata)</pre>
head(s)
```

DOMAINVALUE 1 1	1 1	ID 2398 2331 2410	241 267	294 449	101 215	0	1 1	WEIGHTS 21.38462 21.38462 21.38462
1 1 1	1	2112 2563 2091	173	178	16	0	1	21.38462 21.38462 21.38462

C. Method "spatial"

In cases where units in the sampling frame are geo-referenced and there is spatial correlation among them, it is possible to apply the "spatial" method in the optimization of the frame stratification.

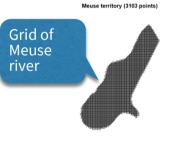

Different steps:

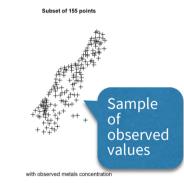

- 1. perform a preliminary spatial analysis and fit spatial models on target variables
- 2. define the sampling frame and add predicted values, prediction errors and coordinates:
- 3. set precision constraints;
- 4. run optimization;
- 5. select the sample.

Spatial analysis

We make use of the «Meuse river» datasets, reporting measures of 4 metals concentration.

```
library(sp)
# locations (155 observed points)
data("meuse")
# grid of points (3103)
data("meuse.grid")
meuse.grid$id <- c(1:nrow(meuse.grid))
coordinates(meuse)<-c('x','y')
coordinates(meuse.grid)<-c('x','y')</pre>
```

Sampling frame

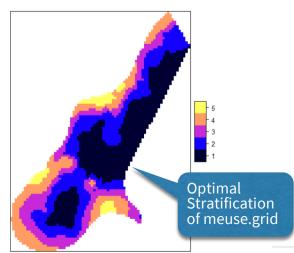

Precision constraints

```
cv2 <- as.data.frame(list(
          DOM=rep("DOM1",1),
          CV1=rep(0.05,1),
          domainvalue=c(1:1) ))</pre>
```

Optimization

```
solution <- optimStrata(method="spatial",
  errors=cv2, framesamp=frame, iter=25,
  nStrata=5, fitting=1, kappa=1,
  range=fit.vgm.lead$var_model$range[2])</pre>
```

```
framenew <- solution$framenew
outstrata <- solution$aggr_strata
frameres <- SpatialPixelsDataFrame(
    points=framenew[c("LON","LAT")],
    data=framenew)
frameres$LABEL <-
    as.factor(frameres$LABEL)
spplot(frameres,c("LABEL"),
    col.regions=bpy.colors(5))</pre>
```

Use of models

Usually, values of target variables are not available in sampling frames, but only of co-variates. In order to calculate correctly the variance of target variables in strata, we can make use of models. When applying methods 'atomic' and 'continuous', it possible to declare linear or loglinear models linking each target variable to one co-variate available in the sampling frame.

Consider the case with 'swissmunicipalities' dataset. Suppose that for all units we only have values for POPTOT and HApoly, while only on a subset (500) of it the values for Surfacesbois and Airbat are also available.

We fit the following models:

```
k <- sample(c(1:2896),500)
s <- swissmunicipalities[k,]
Airind_POPTOT <-
    lm(Airind~POPTOT, data=s)
Bois_HApoly <-
   lm(Surfacesbois~HApoly,data=s)</pre>
```

For both models we calculate heteroscedasticity indexes and variance:

We can now instantiate the values in the 'model' dataframe:

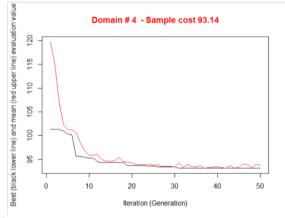

```
model <- NULL
model$beta[1] <-</pre>
      Airind POPTOT$coefficients[2]
model$sig2[1] <- airind[2]^2</pre>
model$type[1] <- "linear"</pre>
model$gamma[1] <- airind[1]</pre>
model$beta[2] <-</pre>
      Bois HApoly$coefficients[2]
model$sig2[2] \leftarrow bois[2]^2
model$type[2] <- "linear"</pre>
model$gamma[2] <- bois[1]</pre>
model <- as.data.frame(model)</pre>
model
# beta
              sig2
                          type gamma
# 0.01109583 0.1708807 linear 0.4703953
# 0.26068155 0.2010272 linear 0.8547931
```

Sampling frame

Optimization

With the same precision constraints of 10% for both target variables we run the optimization step:

```
solution <-
optimStrata(
  method = "continuous",
  errors = cv,
  framesamp = frame,
  model = model,
  nStrata = 5,
  iter = 50,
  pops = 10)</pre>
'model'
dataframe
previously
defined
```

Evaluation

```
framenew <- solution$framenew</pre>
outstrata <- solution$aggr strata</pre>
framenew$Y3 <- framenew$AIRIND</pre>
framenew$Y4 <- framenew$SURFACESBOIS</pre>
val <- evalSolution(framenew, outstrata)</pre>
val$coeff var
       CV2
                 CV3
                        CV4 dom
# 0.0107 0.0706 0.0316 0.0603 DOM1
# 0.0073 0.0364 0.0220 0.0426 DOM2
# 0.0062 0.0252 0.0253 0.0332 DOM3
# 0.0071 0.0328 0.0303 0.0572 DOM4
# 0.0055 0.0646 0.0171 0.0541 DOM5
# 0.0037 0.0745 0.0173 0.0606 DOM6
# 0.0036 0.0753 0.0145 0.0541 DOM7
```

Notice that both the CV's of the co-variates (CV1 and CV2) and the CV's of the real target variables (CV3 and CV4) are compliant to the 10% precision constraints.
